A mosaic thiamine biosynthetic pathway in yeasts reconstructed by multiple horizontal gene transfers

Carla Gonçalves

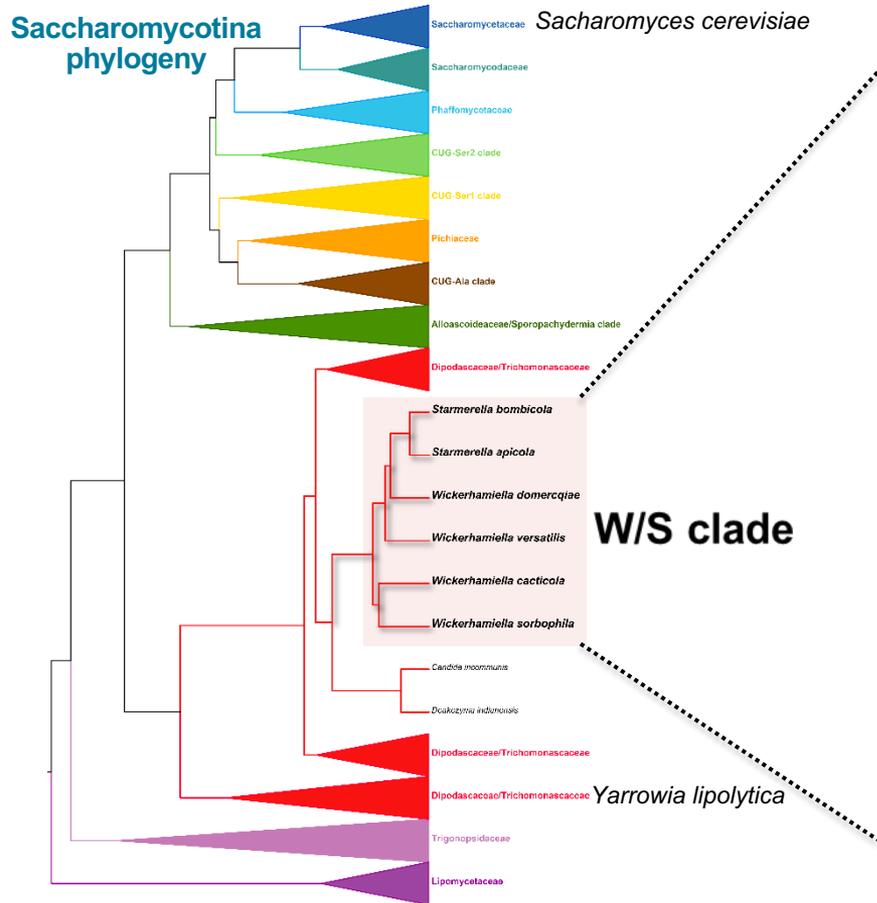

Loss of alcoholic fermentation in a yeast lineage

Taken from JGI

The *Wickerhamiella*/*Starmerella* (W/S) clade

Ecology:

Thrive in sugar (fructose) rich environments

Metabolism:

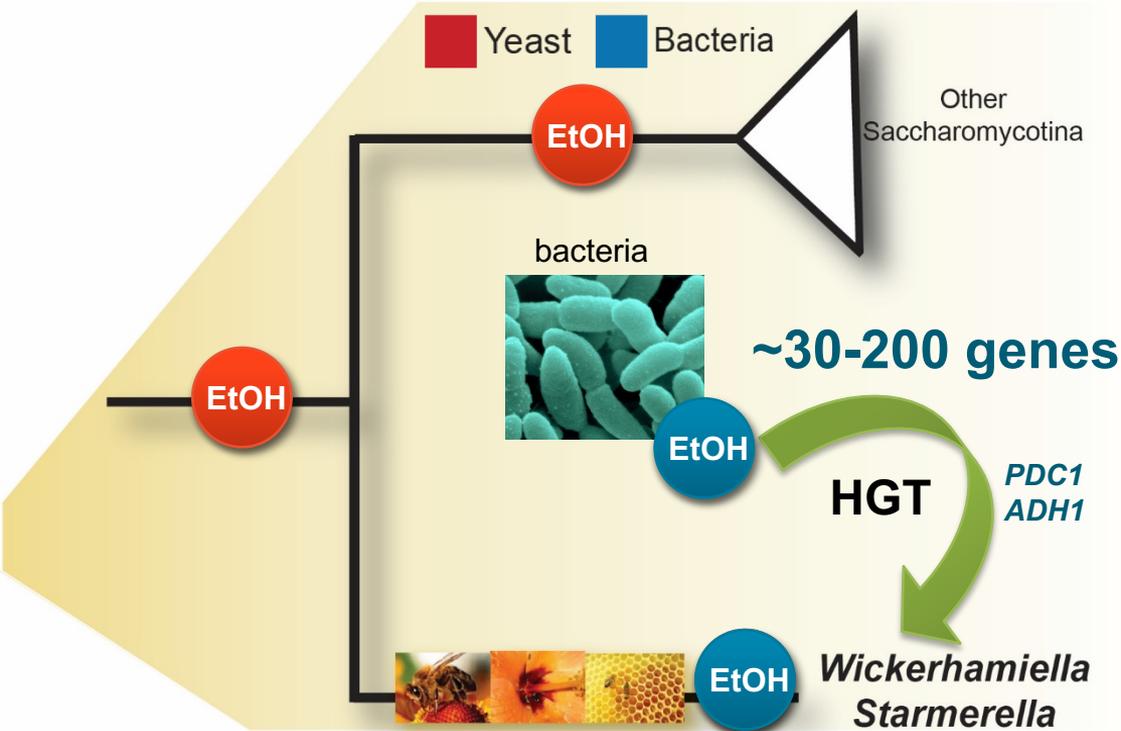

Prefer fructose over glucose (fructophily)

Sophorolipid producers (eco-friendly biosurfactants)

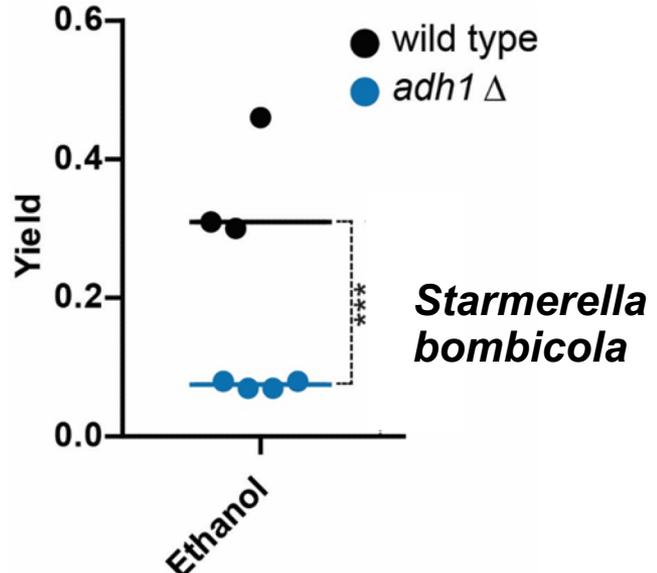

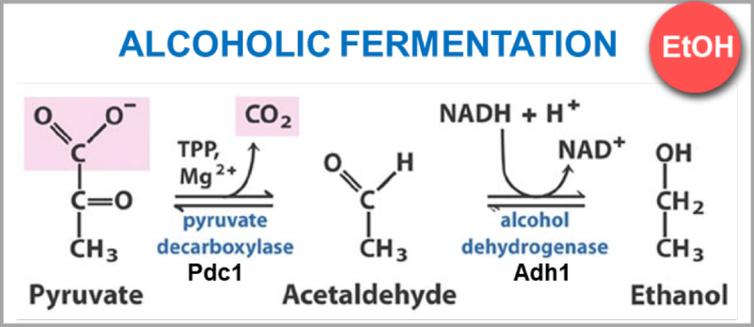

Strong mannitol and erythritol producers

Weak fermenters **But some do ferment!**

Loss and reacquisition of alcoholic fermentation

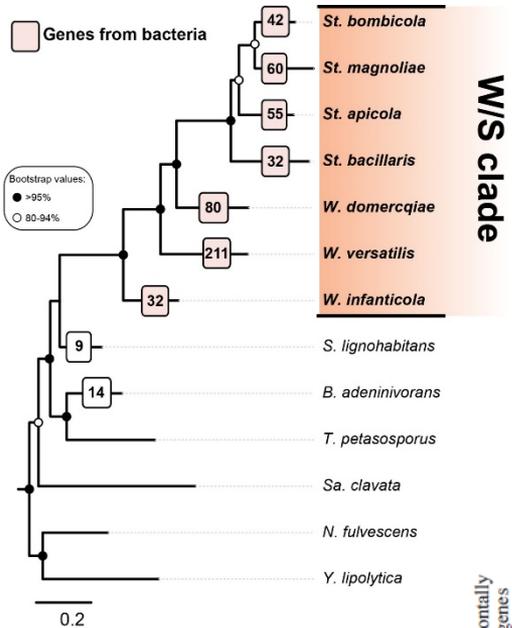

Gonçalves C. et al., 2018, eLife

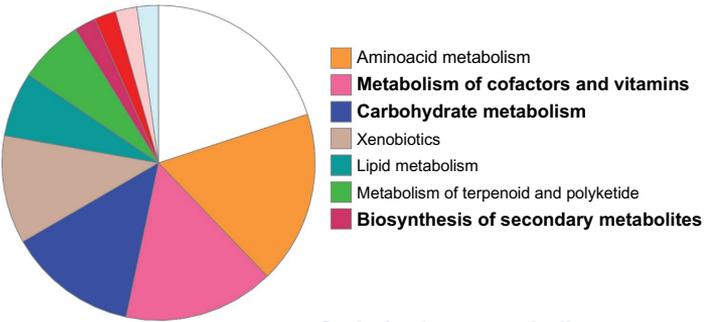

HGT- horizontal gene transfer

Incidence of HGT in the W/S clade

Functional categories of bacterial genes in the W/S clade

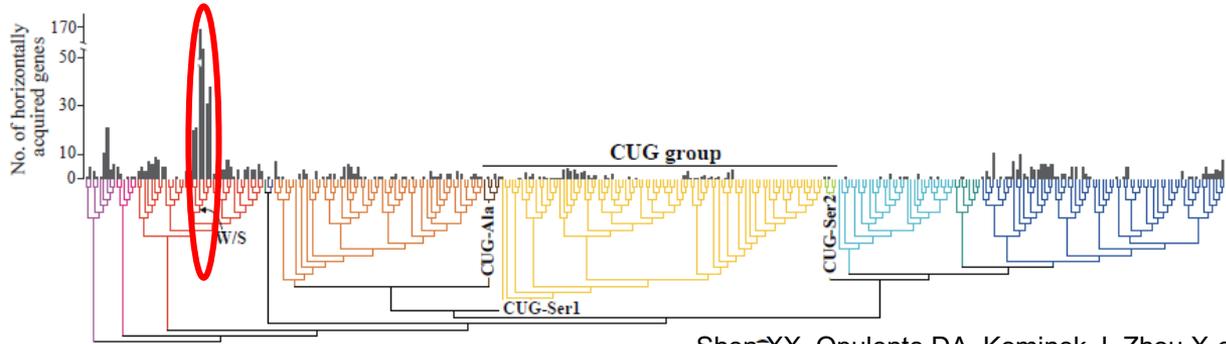

Metabolism of cofactors and vitamins
Thiamine biosynthesis

Carbohydrate metabolism
Gonçalves C. *et al.*, 2018, eLife

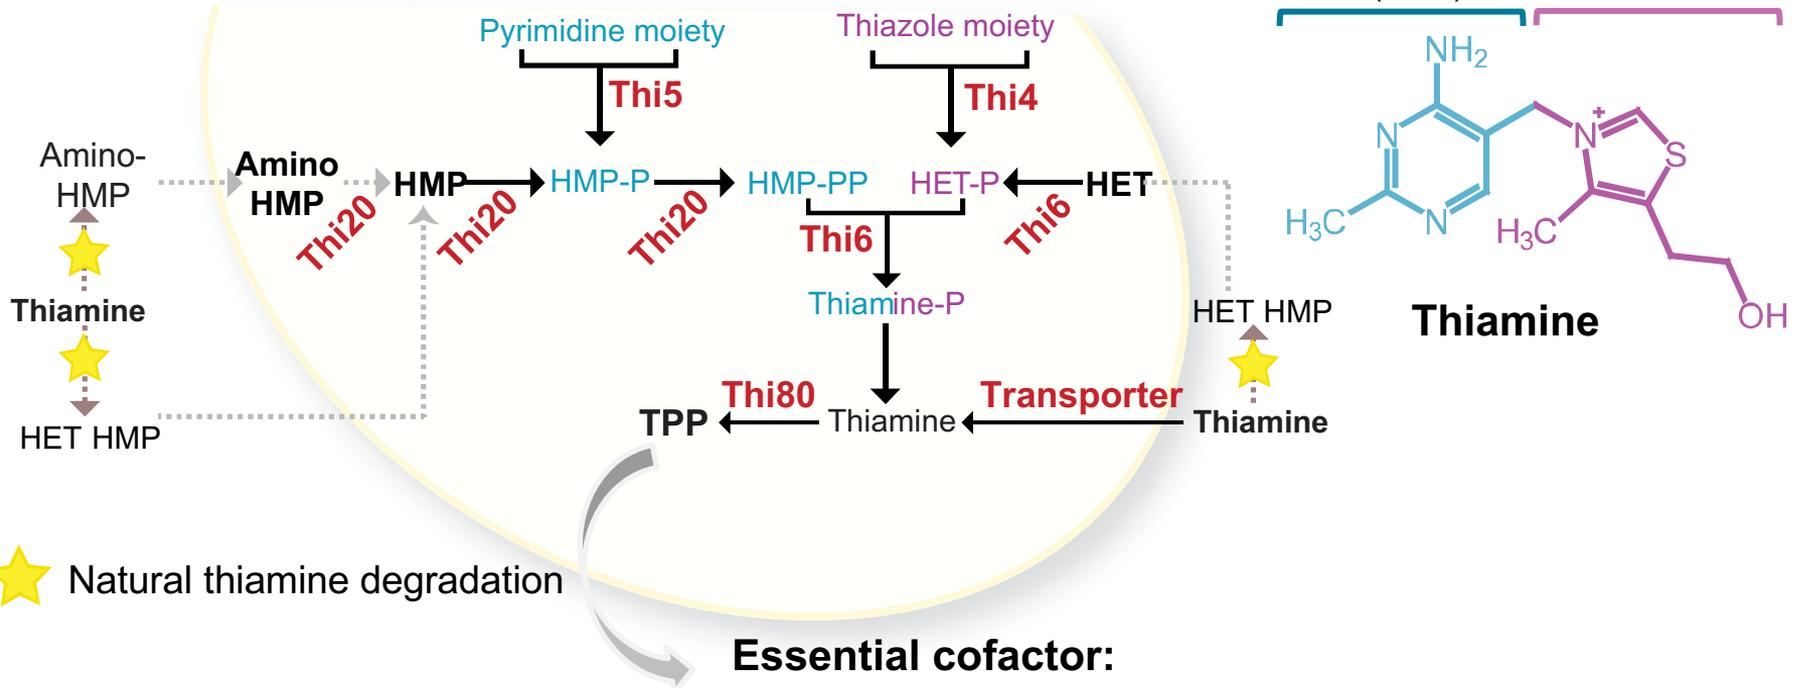

Biosynthesis of secondary metabolites
Kominek J, Droering D, *et al.*, CELL, 2019

Analysis of HGT in 332 yeast genomes

TPP (active form of thiamine) is an essential cofactor

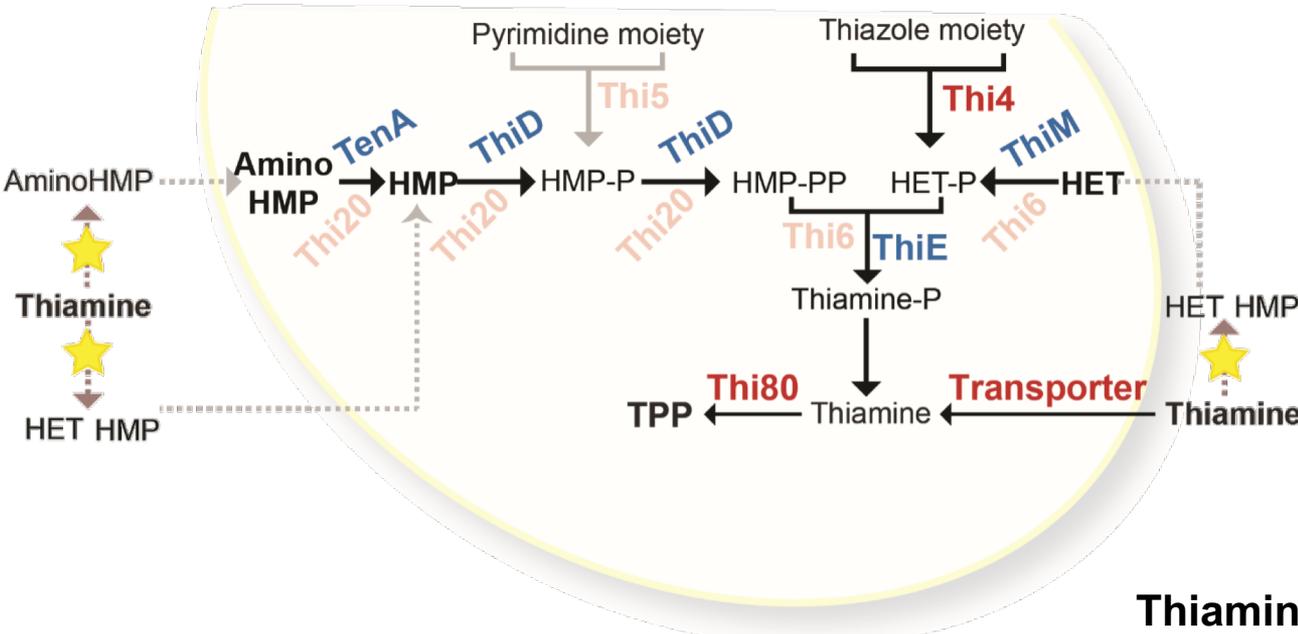

Thiamine biosynthetic pathway in yeasts

★ Natural thiamine degradation

Essential cofactor:
Carbohydrate metabolism
Aminoacid metabolism

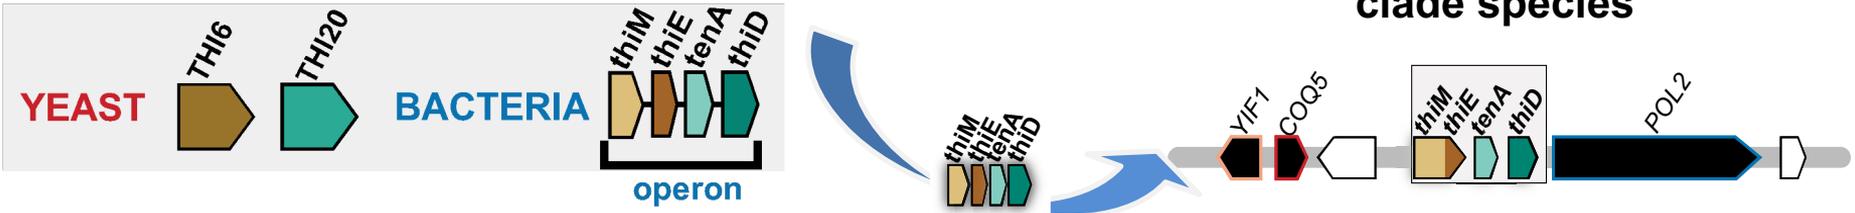

Bacterial genes form a thiamine salvage pathway in W/S yeasts

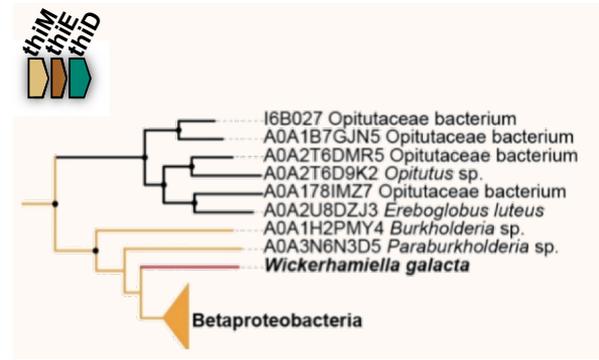

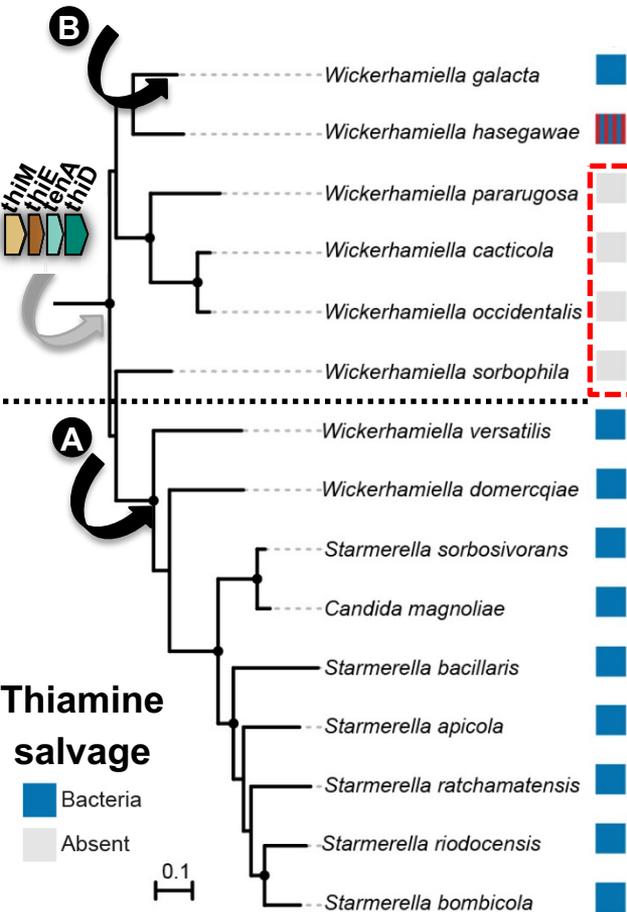

Gene origin
■ Yeast
■ Bacteria

De novo pathway
Salvage pathway
Transport

Thiamine salvage genes are organized in cluster in all W/S-clade species

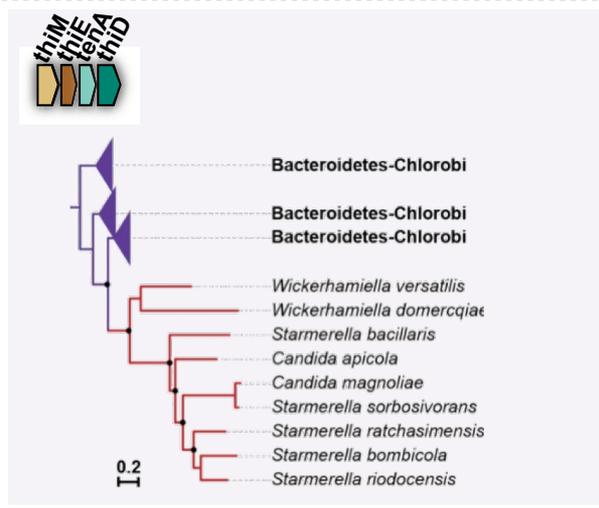

Independent acquisitions of a thiamine operons/genes

Putative donor lineage: Betaproteobacteria

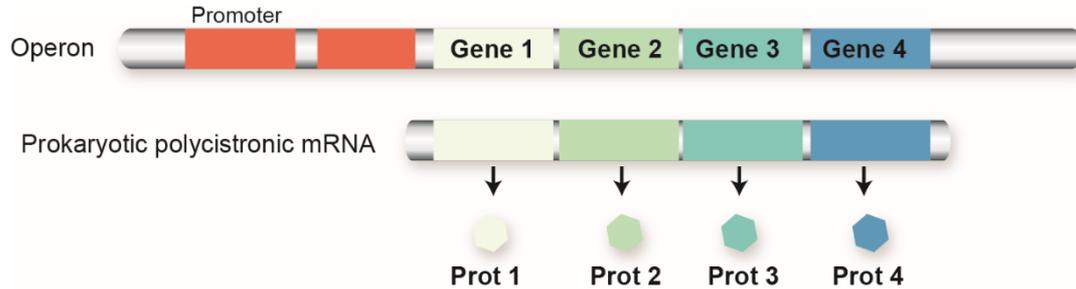

Actinobacteria
independent acquisition of tenA

Putative donor lineage: Bacteroidetes

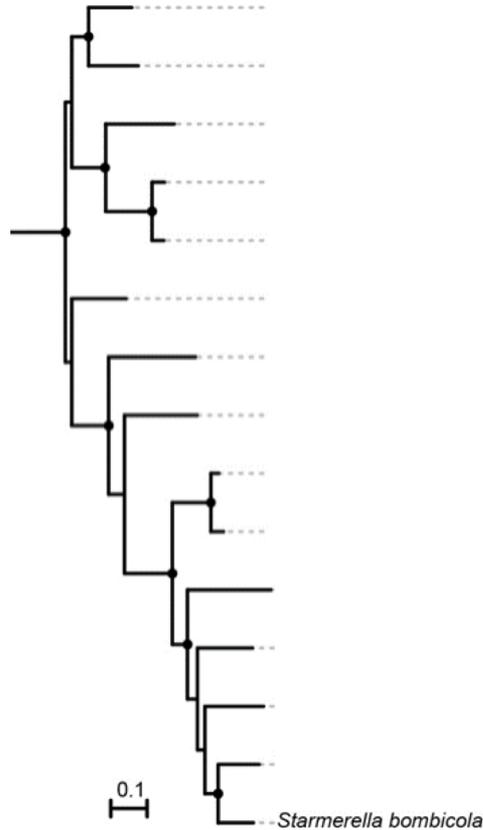

- How did these “operons” evolve in the new eukaryotic setting?

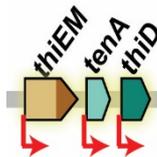

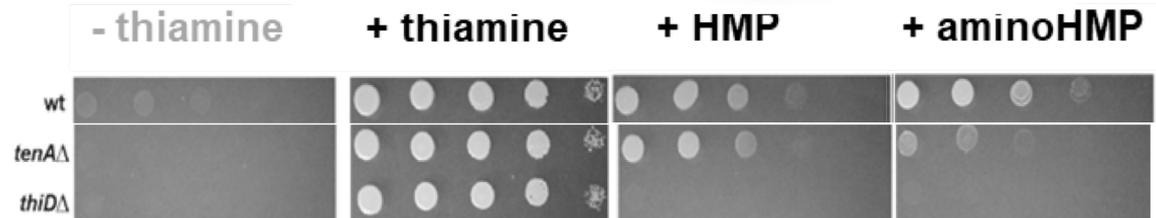

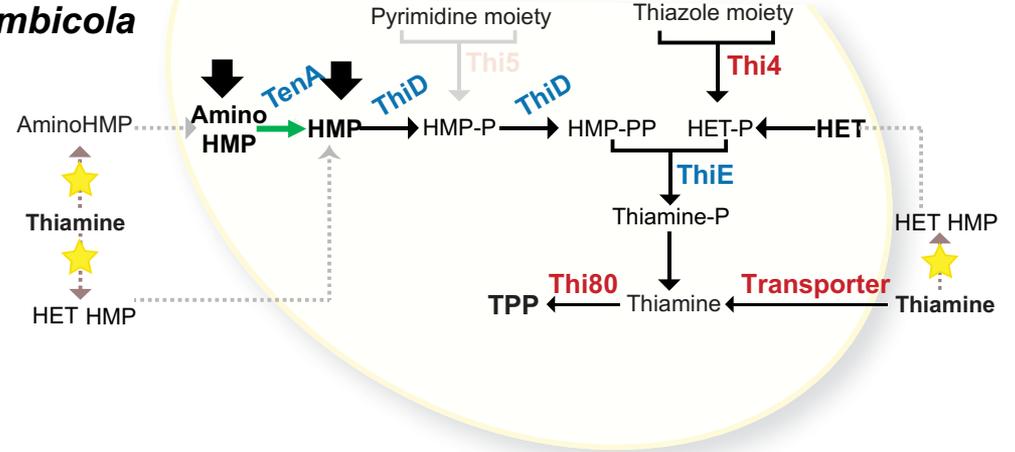

Operons/Polycistronic mRNAs are rare in eukaryotes

- Are they functional?

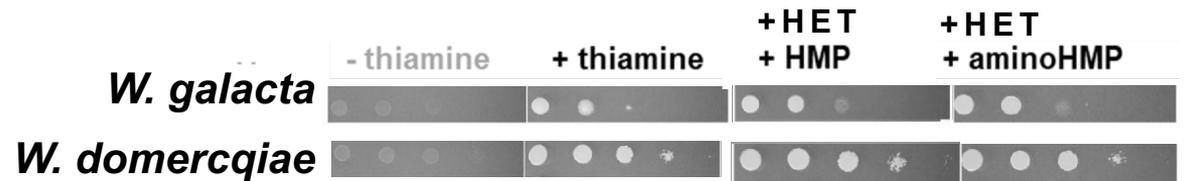

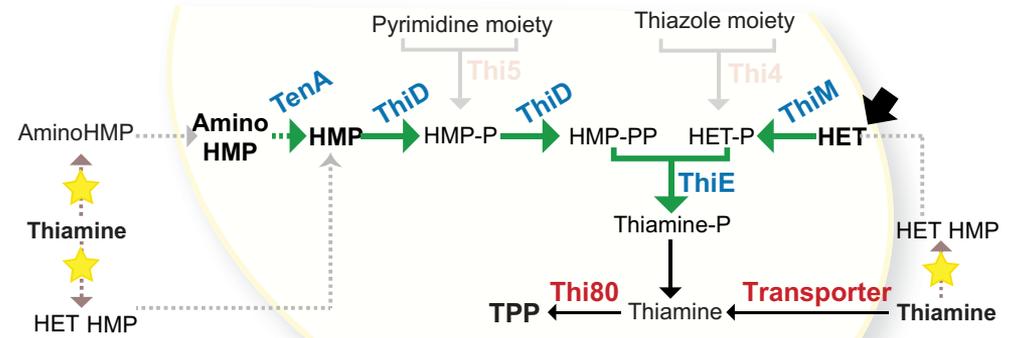

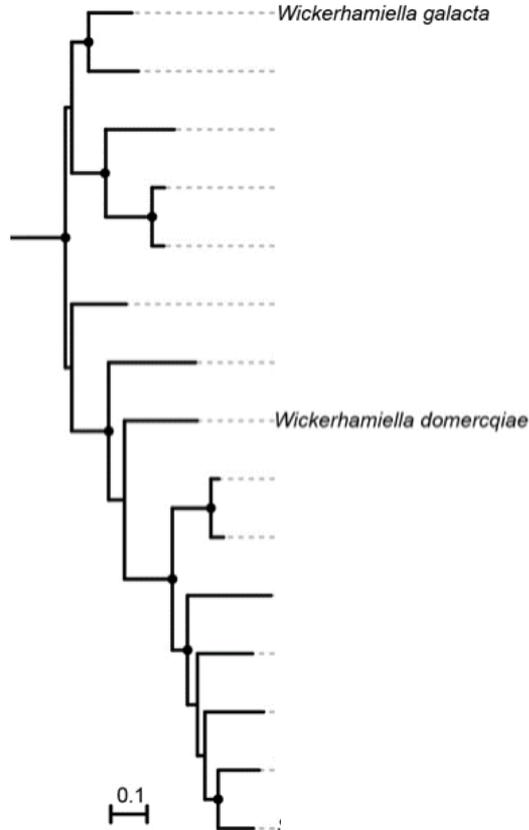

Adaptation and function of thiamine “operons”

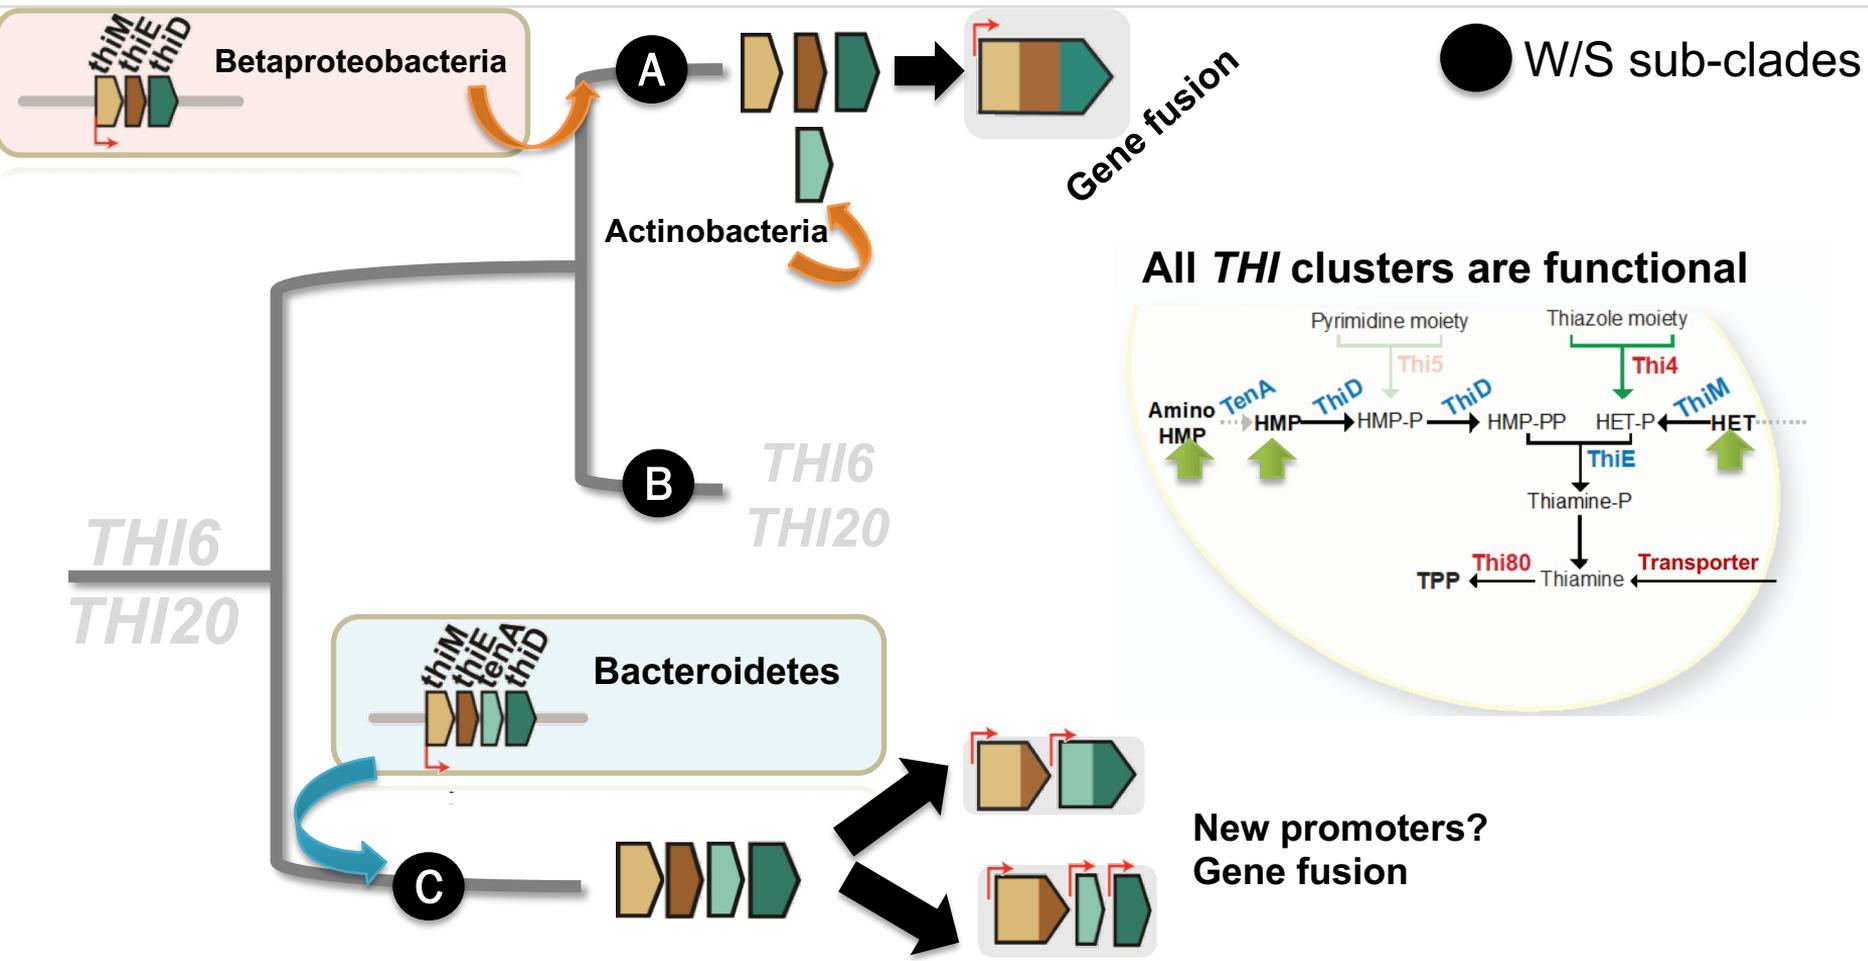

Starmarella bombicola

Adaptation and function of thiamine “operons”
